Introduction

The Pig Health Scheme is a development of the former British Pig Health Scheme (BPHS). The assessors on the scheme monitor English pigs at slaughter for prevalence and severity of disease to help pig producers and their vets to reduce levels of disease within their herds. Individual farm data can be used to benchmark against other members of the scheme. Assessments are carried out by specially trained veterinary assessors at designated abattoirs throughout England, with all of the main pig abattoirs covered as part of the scheme. Assessment dates are published in advance on the AHDB website so producers can make sure their pigs are sent on the designated assessment days.

Membership of the scheme is free to all producers – all they have to do is sign up to the scheme and they will be notified when their reports are generated following an assessment.

This guide gives a brief description of the conditions assessed, the scoring system and an explanation of the reports that members will receive.

Reports can be used to inform and monitor the health status of a producer’s herd and can be used to inform decisions around disease control. Ultimately the aim is to improve the health and welfare of pigs and to help reduce production losses throughout the supply chain. Implementing a health plan is the most cost-effective way to reduce disease.

All Pig Health Scheme members receive the following reports:

1. **Daily report**
   The daily report is produced when an assessment has taken place and is available 48 hours after the assessment.

2. **Quarterly report**
   The quarterly report compiles all of the previous results giving you an overview of your batches for the quarter. This will be available at the end of each quarter.
Using your Pig Health Scheme report

The first report is a basis on which to compare future reports
- Use the data to draw up plans with your vet, nutritionist, marketing group and staff

Subsequent reports can be used as personal benchmarks
- Compare with your unit’s physical performance data
- Be careful when interpreting a single batch report though. It may not be representative of what is happening. However, changes and high scores should be discussed with your vet

Slapmark
If the assessing vet had trouble reading your slapmark, data could be lost.
- Slapmarks should be clearly applied to each front shoulder of the pig
- Ensure all pins are intact, straight and sharp
- Ink the pad well between every pig
- Ensure the slapmark is clean

Good scores
- Continue to monitor herd health closely
- Changes/deteriorations can be identified at an early stage so remedial action can be taken in good time

Poor scores
- Take action
- The cost of individual treatments, additional feed and labour quickly add to production costs and losses at the abattoir
- Poor herd health quickly results in overstocking caused by reduced growth rates

Want to find out more about the scheme and how to join?
Contact the AHDB Health and Welfare team phs@ahdb.org.uk or visit the AHDB website: ahdb.org.uk/pig-health-scheme

Figure 1. A good slapmark: legible before and after slaughter
Figure 2. A poor slapmark. Just a few missing pins can affect the quality
Below is a fictitious example of a Pig Health Scheme individual batch report with explanations for each section.

**Comment box** – alerts you to areas of concern. The quality of the slapmark is recorded here on a scale of 0–2, where 2 indicates good quality markings and 0 indicates poor legibility. It is essential you look at the comments box as certain conditions mentioned may require a discussion with your vet.

‘Pigs submitted’ is the total number of pigs under a given slapmark sent to the abattoir on the specific date. Up to 50 of these pigs are assessed (pigs examined).

Non-coloured boxes indicate low scores, suggesting there are low levels of disease.

Orange areas indicate high levels of disease within a consignment that fall within the highest 30% of national scores.

Yellow areas indicate moderate level of a condition.

---

**Pig Health Scheme Consignment Report**

11 Aug 2022

ZH2256

Perky Pink Pigs III - updated test address cv8 2tl

Porko Meats Ltd

153 pigs submitted

50 pigs examined

**Disease Specific Comments:**

Pleuritis has been found in more than 10% of pigs examined. Veterinary advice is recommended regarding further diagnosis of the possible cause and control of the disease. Affected pigs can have daily liveweight gain (DLWG) reductions of up to 30 g per day, which means an extra 3 days to reach slaughter weight.

Slapmark Score: Slapmarks were clear, which means you are slapmarking correctly. This has enabled us to identify your pigs rapidly and accurately.

---

**Figure 3. Example of an individual batch report**
Check the date of the assessment and slapmark so you know which pigs were assessed.

1. Look at the comments box, what is your slapmark score?

A score of 0 indicates very poor legibility. Herds with repeated scores of 0 will be removed from the scheme. A score of 1 indicates some difficulty in reading the mark.

Take action and check slapmarking equipment.

2. Are there any other comments?

YES

The assessing vet wishes to draw your attention to a possible area of concern

Take appropriate action and/or discuss with your vet.

3. Look at the results with the production performance and health of the particular batch.

Do not interpret the report on its own.

Take into account whether the pigs were the first or last batch of a production group.

Review the overall scores for each condition

Discuss any increasing or high levels with relevant individual(s), e.g. staff and your vet.

4. Look at individual condition scores as well as associations.

Increasing or high scores?

There may be a problem that needs to be addressed

Discuss with your vet.

Some of the conditions assessed can have a serious impact on growth efficiency.
Interpreting the graphs

The graphs show the percentage of pigs with a particular condition from the individual batch, in comparison to your farm average. Scores for individual batches should be monitored against your farm average.

What does your graph look like?

EP-like lesions

EP-like lesions are examined on a scale of 0–55. A score of 0 indicates there are no EP-like lesions and a score of 55 is an indication of extensive EP-like lesions. All pigs examined are given an EP-like score.

Causes for concern

A rise above farm average should be discussed promptly with your vet.

Columns to the right of the graph indicate a high score in this consignment and might indicate a health problem.

The farm average in Figure 4 shows that the herd is generally healthy, with more than 60% of pigs scoring 0 for EP-like lesions. However, this specific consignment of pigs had a particularly high EP-like score of over 60% of pigs scoring 1–10.

Pleuritis association

The graph shows the percentage of pigs with pleuritis (PL) and the percentage found with PL in combination with EP-like lesions (PL+EP) and in combination with pericarditis (PL+PC). The graph also shows the percentage of pigs with milk spot.

Actions

Farm averages need to be monitored

Even a steady increase in the farm average for a particular condition could be decreasing your profits – discuss with your vet before it’s too late.

Causes for concern

High farm averages for specific conditions may indicate a recurring health problem on farm – a discussion with your vet is essential.

Figure 4. Examples from a report of EP-like lesions chart (left) and pleuritis association chart (right)
Disease prevalence

Figures 5 and 6 show example graphs from a report. The black line represents your farm score. You can use these graphs to compare your farm against national scores.

Enzootic pneumonia-like lesions

A farm score or rise in this section of the graph indicates a high level of disease.

You should consider discussing your control plan with your vet.

The higher the EP-like lesion score the greater the impact on growth.

Pleuritis

Pleuritis may be seen in healthy pigs from healthy herds without other conditions.

Average farm scores in this section of the graph indicate an overall disease level of less than 30%.

Figure 6. Pigs with Pleuritis example graph and assessment data
**Lungs**

**Enzootic pneumonia-like lesions (EP-like)**

**What does it look like?**
- Darkened purple/grey areas
- Rubbery areas
- Heavily diseased lungs show a larger proportion of damage

**How is it scored?**
- Score 0 = not present
- Maximum score of 10 for each cranial and middle lobe
- Maximum score of 5 for each caudal and accessory lobe
- Maximum score per pig: 55

**Why might scores vary?**
- New outbreaks of pneumonia
- Unstable health conditions
- Non-vaccinated pigs
- All-in all-out batches of different health status
- Wide variation is unusual in herds that are vaccinated or have stabilised EP
- Similar lesions can be caused by other infections and therefore not all will be true EP, hence ‘EP-like’

The higher the score, the greater the impact on growth efficiency.

Organisms other than *Mycoplasma hyopneumoniae* can cause lesions that are indistinguishable from EP. This will be reported as EP-like lesions on the lungs.

---

**Figure 7. EP-like lesion**

**Figure 8. Diagram of lung lobes**
**Pleuropneumonia (PP)**
- Bacterial disease of the lung and its surface
- Cause: *Actinobacillus pleuropneumoniae* (APP)
- Can be acute (recent) or chronic (long-standing)

**Acute: fresh, active lesions typical of PP**

**What does it look like?**
- Bloody fluid will ooze from the cut surface
- Swollen, firm and dark red

**How is it scored?**
The percentage of pigs and the number of individuals with acute lesions.
- Score 0 = not present
- Score 1 = present

**Chronic: old, established lesions typical of PP**

**What does it look like?**
- Solid black to red raised areas of pneumonia
- Film of pleuritis that might be stuck to the chest wall

**How is it scored?**
The percentage of pigs and the actual number of individuals with chronic lesions.
- Score 0 = not present
- Score 1 = present

**Possible causes**
- Can get acute and chronic in the same batch, depending on when infection occurred
- Can indicate poor biosecurity/hygiene at the unit

**Variation in scores**
- Usually not all pigs are affected at the same time
- Environmental conditions affect levels, e.g. ventilation, humidity, cleaning and disinfection
- The bacteria that cause PP lesions also cause pleuritis; therefore, a rise in the number of pigs with pleuritis may also be seen

**Figure 9. Pleuropneumonia**

**Figure 10. Swollen dark red area of pleuropneumonia**
**Pleuritis (PL)**

Inflammation of the surface of the lungs (the shiny membranes covering the surface); used to be referred to as pleurisy.

**Mild: small areas of inflammation of the lung surface (pleura)**

**What does it look like?**
- Areas appear roughened or stuck together
- Affected area may be stuck to chest wall

**How is it scored?**
The percentage and number of pigs with mild pleuritis are recorded.
- Score 0 = not present
- Score 1 = mild pleuritis present

**Severe: widespread areas of inflammation of the lung surface**

**What does it look like?**
- As above, but involving whole lobes of the lung

**How is it scored?**
The percentage and number of pigs with severe pleuritis are recorded.
- Score 2 = severe pleuritis present

**Possible causes of pleuritis**
- Many bacteria and viruses can cause pleuritis
- Often a combination of bacteria and viruses

**Variation in scores**
- Can be affected by the environment, e.g. poor ventilation and stocking density
- Pleuritis of indeterminate cause is sometimes seen without other accompanying causes

Extra trimming is required, which may result in penalties.

---

Figure 11. Severe pleuritis

Figure 12. Mild pleuritis with fibrous adhesions between the lungs and the ribs (circled)
**Abscess**
Presence of one or more discrete abscesses.

**What does it look like?**
- Pocket of pus
- Sealed off from the remainder of the lung tissues in a thick capsule

**How is it scored?**
The percentage of pigs and the actual number of individuals with the presence of one or more abscesses.
- Score 0 = not present
- Score 1 = present

**Possible causes of abscesses**
- Bacterial infection can often be associated with tail biting, but not always

**Variation in scores**
- An occasional abscess is not unusual
- High or increasing incidences need to be investigated with your vet

A cluster of abscesses may suggest an underlying disease problem on farm.

**Pyaemia**
Bacteria that are spread via the bloodstream to the lungs and elsewhere in the body to cause infection and develop abscesses.

**What does it look like?**
- Lots of small abscesses throughout the lungs

**Note:** Excluding a single abscess. Abscesses may be seen on other areas of the body e.g. joint ill.

**How is it scored?**
The percentage of pigs and the actual number of individuals with small, widely distributed abscesses in the lungs.
- Score 0 = not present
- Score 1 = present

**Possible causes of pyaemia**
- Wounds caused by tail biting, fighting or by sharp objects in the environment
- Other infections

**Variation in scores**
- Increases in aggressive behaviour
- Poor hygiene at injection

Continually monitor the incidence of tail biting and maintain good hygiene during injections and routine procedures.

Figure 13. Abscesses
Figure 14. Pyaemia
**Viral-like lesions**

**What does it look like?**
- Mottled, tan and red in colour
- Affected areas are firm
- Airways may be filled with blood-tinged fluid

**How is it scored?**
The percentage of pigs and the actual number of individuals with viral-like lesions.
- Score 0 = not present
- Score 1 = present
- Severe cases may be mentioned in the comment box

**Common causes of lesions**
- Porcine reproductive and respiratory syndrome (PRRS)
- Swine influenza
- Porcine circovirus type 2 (PCV2)

**Variation in scores**
- Lesions will be seen if infection occurs close to slaughter
- With pigs infected earlier in life, recovery may have occurred and lesions may not be present at slaughter
- A rise in individuals affected may occur in new outbreaks
- Lesions caused by the migration of roundworm larvae can sometimes resemble viral lesions

High or increasing levels should be discussed promptly with your vet.

Figure 15. Viral-like lesions in the lungs
**Pericarditis**

Inflammation of the sac that encloses the heart (pericardium).

**What does it look like?**
- Inflamed, thickened or infected sac
- Fluid or pus in the sac

**How is it scored?**
The percentage and the number of pigs with pericarditis is shown.
- Score 0 = not present
- Score 1 = present

**Possible causes of pericarditis**
- Glässers disease
- Other bacterial diseases such as pasteurellosis, salmonellosis, streptococcal and mycoplasmal infections
- Viruses such as PRRS and influenza

**Variation in scores**
- Prevalence can rise with increasing numbers of cases of pleuritis, as both conditions can share the same causes

An increase in cases or high levels should be discussed with your vet.

Acute outbreaks of Glässers disease can cause high mortality and high production costs.
Liver

Milk spot (*Ascaris suum*)

What does it look like?
- Splashes of milk or cream on the surface of the liver

How is it scored?
- The percentage and number of pigs infected in the batch are recorded.
- Score 0 = not present
- Score 1 = present

Possible causes
- Large roundworms migrating into the liver
- Presence at slaughter demonstrates recent infection – lesions disappear after 25 days

Variation in scores
- Wide fluctuations in numbers can be seen from one batch to another
- The timing of infection varies depending on the number of eggs carried (worm burden)

- The time of year – infectivity of eggs is temperature-related. Roundworm eggs are very persistent in the environment
- The timing of treatment, pig-flow management and the frequency of building cleansing and disinfection
- Lung scores may rise as larvae can migrate through the lungs, causing lesions similar to those of viral lesions
- Contaminated pens are the most common source of infection. Targeted cleansing and disinfection is critical for prevention
- Severe worm infestations are usually associated with the poorest levels of hygiene. This can have a significant effect on growth and feed efficiency

Prevention of environmental contamination is critical.

Figure 18. Milk spot

Figure 19. Milk spot
**Hepatic scarring**

Hepatic scarring results from fibrous tissue building up in the liver.

**What does it look like?**
- Faint scar-like marks on the surface of the liver

**How is it scored?**
The percentage and number of pigs with scarring on the surface of the liver are shown.
- Score 0 = not present
- Score 1 = present

**Possible causes of hepatic scarring**
- Whilst the cause is unknown, scarring could be due to the healing of 'milk spots' caused by worms

**Variation in scores**
- This may indicate a roundworm infection

**Peritonitis**

Infection and inflammation of the membrane that covers all the organs and surfaces in the abdomen (the peritoneum), including the liver.

**What does it look like?**
- Inflammation of the liver surface
- Organs and intestines may ‘glue’ together

**How is it scored?**
The percentage and number of pigs affected are shown.
- Score 0 = not present
- Score 1 = present

**Possible causes of peritonitis**
- Often bacterial infections, e.g. streptococcal infection and Glässers disease
- Damage from the migration of roundworms may also cause peritonitis

**Variation in scores**
- May range from mild inflammation of the liver surface to all organs and intestines sticking together
- Usually individuals (rather than groups) affected

*Increased levels may warrant further investigation with your vet.*

---

**Figure 20. Peritonitis**

**Figure 21. Hepatic scarring**
Tail biting Web-based Husbandry Advisory Tool (WebHAT)

This is an interactive resource providing specific information tailored to your farm which you can use to build your own tail biting risk report.

This uses the information you have provided about the key risks and provides practical suggestions to help reduce these risks on farm.

Visit: webhat.ahdb.org.uk
Papular dermatitis

What does it look like?
• Small, raised red spots on the skin

How is it scored?
• The average score, the number of pigs affected and the percentage of pigs affected is shown
• Score 0 = not present
• Score 1 = present

Possible causes of papular dermatitis
• A very common cause is sarcoptic mange. Without investigation presence on farm cannot be confirmed
• Insect bites, harvest mites and larvae
• Urine scald

Variation in scores
• Scores can vary depending on the time of year, environmental conditions and the type of housing
• If the cause is mange, lesions tend to have a distinct distribution on the body and score may vary depending on the treatment programme in place
• Occasionally, the process of scalding and de-hairing can prevent scoring or accentuate lesions

Discuss mange control with your vet.

AHDB is a statutory levy board funded by farmers and others in the supply chain. Our purpose is to be a critical enabler, to positively influence outcomes, allowing farmers and others in the supply chain to be competitive, successful and share good practice. We equip levy payers with easy-to-use products, tools and services to help them make informed decisions and improve business performance. Established in 2008 and classified as a Non-Departmental Public Body, AHDB supports the following industries: meat and livestock (Beef, Lamb and Pork) in England; Dairy in Great Britain; and Cereals and Oilseeds in the UK. For further information visit ahdb.org.uk
